A Synthetic Study of Signal Gain

This authored sample tests bilingual reading. It is not a real research publication. We preserve source locations and report uncertainty.

We measure signal gain in a controlled experiment. The input power is 2 watts. The output power is 6 watts. The result supports a gain of 3 for this setup. This observation does not establish performance under other conditions.

The method compares the input and output under the same conditions. Figure 1 shows the measured signal. Table 1 records the two power measurements. The equation defines the ratio. No additional experiments are claimed.

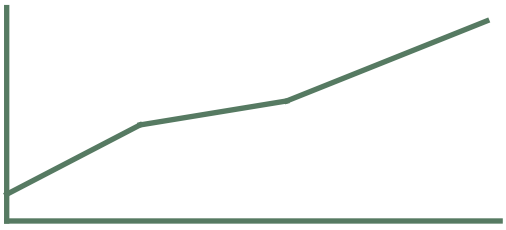

Fig. 1. Signal measured in the authored example.

$$G = P_{out} / P_{in}$$

Table 1. Power measurements.

Quantity	Watts
Input	2
Output	6

The sample is designed to exercise figure crops, table crops, equation images and stable page anchors. Readers should inspect the original evidence before drawing conclusions.

Methods and limitations

We measure signal gain in a controlled experiment. The input power is 2 watts. The output power is 6 watts. The result supports a gain of 3 for this setup. This observation does not establish performance under other conditions. We measure signal gain in a controlled experiment. The input power is 2 watts. The output power is 6 watts. The result supports a gain of 3 for this setup. This observation does not establish performance under other conditions.

The evidence is limited to an illustrative example. All text and graphics were authored for testing. This page checks that the reader does not stop after the first page. The original source file must remain unchanged after processing.

Data availability: This synthetic sample contains no personal data. Code availability: The extraction and validation workflow is part of the desktop application. Competing interests: This is a software test fixture.
